

Methadone - General Effects

Methadone is a narcotic analgesic and central nervous system (CNS) depressant.

1. Methadone is prescribed for the relief of moderate to severe pain and maintenance therapy for narcotic dependency.
 - a. Methadone has a half-life of 15-55 hours.
 - b. Methadone has a general therapeutic range, but experienced effects can vary based on an individual's prescription history.
 - i. Therapeutic range refers to the blood concentration expected to achieve the desired therapeutic effects. Due to many factors such as prescription history, dosage, tolerance, drug-drug interactions and use, an individual may exhibit signs of impairment even though blood concentrations fall within the therapeutic range.
2. General effects of narcotic analgesics and CNS depressants include but are not limited to: nausea, vomiting, respiratory depression, sedation, and mental clouding/mood swings.
3. General effects of narcotic analgesics and CNS depressants on driving include, but are not limited to: impaired divided attention, poor coordination, cognitive impairment, delayed reaction time, difficulty following direction, and falling asleep at the wheel.
4. The longer an individual uses a drug, the more they can build up a tolerance to its effects. Tolerance occurs when an individual no longer responds to the drug in the way that they initially responded. When an individual gains tolerance to a drug, a higher dose of the drug is necessary to achieve the same level or response initially achieved. As tolerance is gained, it may reduce some of the possible negative effects of a drug.
5. Drug metabolism (alcohol excluded) exhibits first order kinetics, or the elimination of a constant fraction of drug quantity per unit of time, which means that the amount eliminated is proportional to the drug concentration.
6. The use of more than one drug at a time may enhance the effects the drugs would otherwise have on their own, leading to greater impairment.
